Women’s Pathways to Jail: Examining Mental Health, Trauma, and Substance Use

By Shannon M. Lynch, Ph.D., Idaho State University; Dana D. DeHart, Ph.D., University of South Carolina; Joanne Belknap, Ph.D., University of Colorado; Bonnie L. Green, Ph.D., Georgetown University

Study Introduction

The rate of incarceration of women has increased substantially in recent decades, with a 31 percent increase between 2000 and 2011 (Minton, 2012). Female offenders appear to have different risk factors for offending than do male offenders. In particular, female offenders report greater incidence of mental health problems and serious mental illness (SMI) than do male offenders (James and Glaze, 2006; Steadman et al., 2009). Female offenders also report higher rates of substance dependence as well as greater incidence of past physical and sexual abuse (James and Glaze, 2006). Other researchers also have noted elevated rates of experiences of interpersonal trauma, substance dependence, and associated symptoms of post-traumatic stress disorder (PTSD) in female offenders (Green et al., 2005; Lynch et al., 2012).

This multisite study addresses critical gaps in the literature by assessing the prevalence of SMI, PTSD, and substance use disorders (SUD) in women in jail, and the pathways to jail for women with and without SMI.

Methods

Using a randomly selected sample (N = 491) from rural and urban jails, this study employed the Composite International Diagnostic Interview (World Health Organization, 1990)—a structured diagnostic interview—to assess current and lifetime prevalence of SMI (including major depression and bipolar and psychotic spectrum disorders), PTSD, and SUD of women in jail. Women’s prior access to treatment and their level of functional impairment in the past 12 months were also assessed to better inform the understanding of their current treatment needs.

Next, qualitative Life History Calendar interviews were conducted with a subset of the sample (N = 115) to explore women’s pathways to jail to examine how onset of different types of criminal activity and delinquency vary as a function of mental health status and trauma exposure.

Finally, project investigators interviewed corrections staff members at participating jail sites to better assess the staff members’ beliefs about the prevalence of mental health difficulties in women in jail as well as their perceptions about women’s pathways to jail.

KEY POINTS

- Trauma and mental health issues were associated with the onset of crime.
- A majority of women in jail had at least one of the assessed mental health disorders in their lifetime.
- One in four women met criteria for lifetime serious mental illness (SMI), post-traumatic stress disorder (PTSD), and substance use disorders (SUD).
Part I: The Structured Diagnostic Interviews (N = 491)

Notably, 43 percent of participants met criteria for lifetime SMI, and 32 percent met criteria for SMI in the past 12 months. SUDs were the most commonly occurring disorders; 82 percent of the sample met lifetime criteria for drug or alcohol abuse or dependence. Similarly, PTSD rates were high; just over half of the sample (53 percent) met criteria for lifetime PTSD. Women also met criteria for multiple lifetime disorders at high rates (see figure).

Finally, 30–45 percent of individuals who met criteria for a current disorder reported severely impaired functioning associated with SMI, PTSD, or SUD in the past year. The majority (78–84 percent) of the participants who met criteria for an SMI such as major depressive or bipolar disorders had talked with a mental health professional, and most indicated it was effective. In contrast, closer to half of the individuals with PTSD or substance-related problems indicated that they had talked with mental health professionals about these difficulties.

Women with SMI demonstrated significant effects or trends in risk for onset of substance use, drug dealing/charges, property crime, fighting/assault, and running away. In addition, experiences of victimization predicted risk of offending. Specifically, intimate partner violence contributed to risk for commercial sex work/trading sex and drug dealing/charges. Witnessing violence contributed to risk for property offenses, fighting/assault, and using weapons. Finally, caregiver violence contributed to risk for running away.

Part II: Life History Calendar Interviews (N = 115)

SMI demonstrated significant effects or trends in risk for onset of substance use, drug dealing/charges, property crime, fighting/assault, and running away. In addition, experiences of victimization predicted risk of offending. Specifically, intimate partner violence contributed to risk for commercial sex work/trading sex and drug dealing/charges. Witnessing violence contributed to risk for property offenses, fighting/assault, and using weapons. Finally, caregiver violence contributed to risk for running away.

Part III: Staff Interviews (N = 37)

Corrections staff (including supervisors, health practitioners, and corrections officers/deputies) indicated a general recognition that women's experiences of victimization were linked with their entry into the criminal justice system. Furthermore, many staff were aware of women's mental health difficulties. In particular, they expressed concern that there were limited resources in jail for women with mental illness, and that women were then released from jail with little to no assistance (e.g., housing or programs) to support their attempts to change behavior and lifestyle.
Discussion

This national sample of women in jails demonstrated high rates of mental health problems, with a majority of the participants meeting diagnostic criteria for lifetime SMI, PTSD, and/or SUD.

Similar to Steadman and colleagues’ (2009) finding that 31 percent of female offenders residing in northeastern jails met criteria for a current SMI, this multisite study found that 32 percent of participants met criteria for an SMI in the past year. Furthermore, the number of women meeting criteria for multiple lifetime and current disorders was high. The prevalence of SMI, PTSD, and SUD—as well as high rates for co-occurring disorders—suggests that female offenders enter (or reenter) jail with substantial and often multiple mental health concerns and subsequently have complex treatment needs.

Although more than half of the participants indicated prior access to treatment, a significant portion of female offenders did not appear to have accessed treatment that addressed their problems or helped them to improve their basic level of functioning. The levels of reported impairment—combined with the frequency of SMI, PTSD, and SUD rates—suggest the critical need for additional resources for mental health assessment and treatment of this population.

The women with SMI reported significantly greater frequency of all forms of victimization and more extensive criminal histories. As was demonstrated in the SEM analyses, women’s experiences of child and adult trauma were significant predictors of their overall mental health. Results of the SEM analyses also suggest that whereas child and adult victimization related directly to women’s mental health, victimization did not directly predict offending history—only mental health was directly associated with women’s offending histories.

In addition to identifying this clear link between mental illness and offending history, the data provided via the in-depth Life History Calendar interviews demonstrate how SMI is associated with increased risk of the onset of a number of offending behaviors and how this is exacerbated by experiences of victimization and drug use. Women with SMI were at higher risk for numerous forms of offending, including running away, substance use, and drug dealing/charges. In addition to the increased risk associated with SMI, various forms of traumatic victimization predicted the onset of offending.

Understanding female offenders’ pathways to offending, including both risk for onset and risk for continued offending, helps elucidate the complexity of this population’s experiences and identify key factors and intervening variables that may ameliorate or exacerbate risk. Research in this area is critical to the development of gender-responsive programming (Hills et al., 2004), alternatives to incarceration, and problem-solving court initiatives.
Childhood and adult victimization appears to increase the risk of experiencing mental health problems, which in turn is related to increased likelihood of criminal offending.

About the Authors

Shannon M. Lynch, Ph.D., is Professor of Psychology at Idaho State University. Her research interests include consequences of exposure to interpersonal violence and survivors’ use of resources to cope with and recover from traumatic events. For the past several years, her research team has conducted a series of quantitative and qualitative projects examining incarcerated women’s trauma exposure, mental health, and treatment needs.

Dana D. DeHart, Ph.D., is on the research faculty of the University of South Carolina’s College of Social Work. She has been Principal Investigator on grants and contracts addressing victimization and survivor services, the impacts of incarceration, the gendered pathways to adult and juvenile offending, and predatory sexual behavior. Dr. DeHart has expertise in a range of qualitative and quantitative methods.

Joanne Belknap, Ph.D., is Professor of Sociology at the University of Colorado–Boulder. She is the author of numerous articles and the book, *The Invisible Woman: Gender, Crime, and Justice*, now in its third edition. Dr. Belknap is the 2014 President-Elect of the American Society of Criminology.

Bonnie L. Green, Ph.D., is Professor and Vice Chair for Research in the Department of Psychiatry and Associate Dean for Faculty Development at Georgetown University Medical School in Washington, D.C. She has studied the consequences of traumatic events for several decades. Her current research focuses on the mental health needs of uninsured populations and delivering mental health interventions in primary care.
